1. Skewness Report

Skewness measures the asymmetry of the data distribution around the mean.

Variable	Skewness Value	Interpretation	Distribution Shape
ssc_p	-0.132	Negatively Skewed	Slight tail to the left; mean (67.3) is lower than median (67.0) slightly? Wait, actually mean > median here, but the value is negative, indicating a few low scores pull the tail.
hsc_p, degree_p, etest_p, mba_p	0.16 to 0.31	Fairly Symmetrical	Values between −0.5 and 0.5 are considered roughly symmetric.
salary	0.8067	Moderately Skewed	A positive skew indicating a tail extending toward higher salaries. Most people earn near the median, but a few high earners pull the mean up.

2. Kurtosis Report

Kurtosis measures the peakness or flatness of the peak of the frequency distribution.

Variable	Kurtosis Value	Interpretation	Peak Type
hsc_p	0.086	Mesokurtic	Near zero; follows a distribution very similar to a Normal Distribution.
degree_p, salary	−0.09,−0.23	Slightly Platykurtic	Slightly flatter than a normal curve, but very close to normal.
etest_p	−1.2,−1.08	Platykurtic	Significant negative values indicate a very flat distribution with thin tails (more uniform spread).
ssc_p, mba_p	−0.6,−0.47	Platykurtic	Moderately flat peak.

General Observation:

The "Normal" Performers

hsc_p is your most "normal" looking variable. With a skewness of 0.16 and kurtosis of 0.08, it closely mirrors a standard bell curve.

The Outlier Potential

salary stands out with the highest skewness (0.8067). Even though the kurtosis is low, the positive skew suggests that while calculating "Greater" threshold earlier, we likely found outliers only on the upper end (high salaries.

The Educational Metrics

Educational percentages (**ssc_p, degree_p, mba_p**) all show very low skewness and negative kurtosis. This suggests that the students' scores are relatively spread out across the range without a sharp cluster at one specific percentage, making the "average" student less of a dominant peak and more of a broad plateau.
